EBS

Software Application Enabling Preoperative Planning and Training for Bone Fracture Reduction Medical Procedures Based on Real Patient Data

User's Manual

A guide for preoperative planning of bone fracture medical procedures with EBS

Manual for EBS Version 0.7.0

Contents

User's Manual

Welcome to the EBS user's manual. EBS is a software application for preoperative planning of bone fracture medical procedures based on a real patient data.
This manual is a guide through the concepts and building blocks of the application. It also serves as a reference for a standard application procedures.

EBS operates on a real patient data. CT examination in form of DICOM files is accepted as an input. 3D mesh models are build from the examination in segmentation process. While the segmentation is largely automated it still requires some user input. The 3D mesh models of bone fragments can be viewed in any arbitrary 3D projection as well as manipulated as to simulate reduction. Fixation plates and screws can be inserted into the model.

Get acquainted with Terminology, User Interface and start using EBS.

To access full functionality, EBS requires to be activated.

Terminology

Dataset Medical examination comprising of a stack of slices.

Label Set of voxels in dataset. Labels are used to represent elements of interest e.g. bone fragment. Label shape can be visualized in 3D.

Slice Two dimensional image containing cross-section trough the body.

Voxel A single pixel, cell in the slice grid.

User Interface

EBS main window comprises of a toolbar on the left hand side, a document view area on the right hand side and the main menu at the top of the window.
Document viewing and editing is done by executing commands, using the tools and manipulating widgets. User Interaction describes the distinction between those in detail.

Global options can be set using Options Dialog.

Toolbar
Toolbar on the left hand side

The toolbar contains tools and commands for viewing and editing of the document. The top part of the toolbox contains tools and commands for view manipulation - View Toolbox including a panel with properties for the currently active view. Below the panel is a task selector which shows additional tools and commands based on task selected:

- Segmentation :
    - Segmentation Toolbox
    - Labels Toolbox
- Reduction :
    - Reduction Toolbox
- Analysis .

At any time Object List or Selection attributes might be displaying as well.

View Toolbox

Slice Tool

Click and/or drag mouse in a view to change the slice position. In slice and 3D view mouse

Shortcut: click or drag will display slice at the position pointed by mouse.

6

Z   This tool can be also temporarily activated by clicking on the middle mouse button.

View Pan Tool

Click and drag to pan the view.
This tool can be temporarily activated by holding Alt + middle mouse button.

Shortcut:
X

View Zoom Tool

Click and drag to zoom the view.
This tool can be temporarily activated by holding Alt + left and middle mouse button.

Shortcut:
C

View Rotate Tool

Click and drag to rotate the 3D view. In dataset view this tool changes view projection.

Shortcut:
V

Viewpoint widget

Viewpoint widget can also be used to to change the viewpoint: click on surface to rotate the viewpoint to one of the predefined view orientations or drag to rotate freely.
This tool can be temporarily activated by holding Alt + left mouse button.

View Reset

Click to reset the selected view to default.

Segmentation Toolbox

Region Of Interest Tool

Define region of interest (ROI) - a volume which is used in further processing. ROI can be defined by manually by entering coordinates in tool panel or by dragging a mouse in dataset view. Drawing region in dataset view will modify only two dimensions of ROI, dimensions which are displayed in the view with the third one - depth - left unmodified. To draw all three dimensions bounding box has to be drawn in two dataset views displaying different orientation. Region is indicated by red rectangle.

Filter

Filter the dataset with low-pass filter. Dialog box offering filters is shown. There are 3 distinct

7

smoothing filters available:

- **Recursive Gaussian** - this filter is using ITK RecursiveGaussianImageFilter filter to process the dataset.

- **Gradient Anisotropic Diffusion** - this filter is using ITK GradientAnisotropicDiffusionImageFilter to process the dataset.

- **Curvature Anisotropic Diffusion** - this filter is using ITK CurvatureAnisotropicDiffusionImageFilter to process the dataset.

Segmentation Tool

Segmentation tool creates initial label from the dataset based on voxel values. The tool sets a threshold value for the threshold filter. The threshold edge is drawn on the slice. Segmentation will be executed with a click on Apply button in the tool panel. Based on selected options some of the following filters might be executed on the label as a post processing step:

- **Opening** - ITK BinaryMorphologicalOpeningImageFilter

- **Opening by reconstruction** - ITK OpeningByReconstructionImageFilter

- **Hole filling** - ITK VotingBinaryIterativeHoleFillingImageFilter followed by GrayscaleFillholeImageFilter It is recomended to Select at least one opening filter as this will remove small isolated fragments which are usually artifacts of thresholding. **Clear all existing labels** will remove labels that are already there before the filter is run.

Segmentation Wizard

Wizard opens a new tool panel and guides a user trough steps of segmentation process as described in Segmentation task.

Labels Toolbox

Labels are parts of whole volume which are of interest.
For the most part labels can be interpreted as bone fragments. EBS offers tools to create and manipulate labels. Initial label is usually created with Segmentation Tool.

Select Tool

Shortcut: Q

Click on label in Dataset or 3D view to select it. Hold Shift while clicking to add to selection or Ctrl to remove object from selection. This tool can be used to select other types of objects as well. An alternative way to select objects is by clicking in the items in Objects box in the toolbox.

New Label

Create new, empty label.

8

Merge Labels

Merge selected labels into a new label.

Delete Label

Delete selected labels.

Paint Tool

Manually paint selected label. Painting is done in Dataset view. The tool shows options box with following settings:

- **Paint over** defines which objects to paint over.
- **Clear label** when set painting will clear the label.
- **Size** defines size of paintbrush in voxels.
- **3D** when selected the painting is done in multiple slices at once.
- **Isotropic** takes voxel physical size in each direction into account when size is defined.
- **Round** or **Square** defines a brush shape.

Fill Hole Tool

Click on hole to fill it. The tool works only on a single slice. The tool will not perform when hole is not closed.

Separate

Move spatially un-connected volumes in selected label into separate labels.

Split Tool

Split label into multiple labels based on seed points. Based on dataset labels grow from seed points. The seed points can be defined in dataset or 3D view. When seed point is clicked in 3D view it may move away from clicked point. This is to assure the optimal placement. Verify that seed point is still inside object to be separated. Split Tool uses ROI. For further instructions see an example.

Cut Tool

Cut label by drawing a cutting plane. One or more cutting planes can be defined by clicking on the 3D view. Object separated will lay in one of the partitions of the cutting planes. For further instructions see an example.

Split Tool Example

This is a step-by-step example of Split Tool usage on a case of splitting pelvis into separate bone fragments.

Split Tool can be used to split label based on Dataset. It works by specifying seed points on or in the label from which volumes are grown. The growth is determined by dataset values. The two growth regions will meet in the least dense value in the dataset - usually a crack. Starting point for this example is a label obtained from Segmentation Wizard.
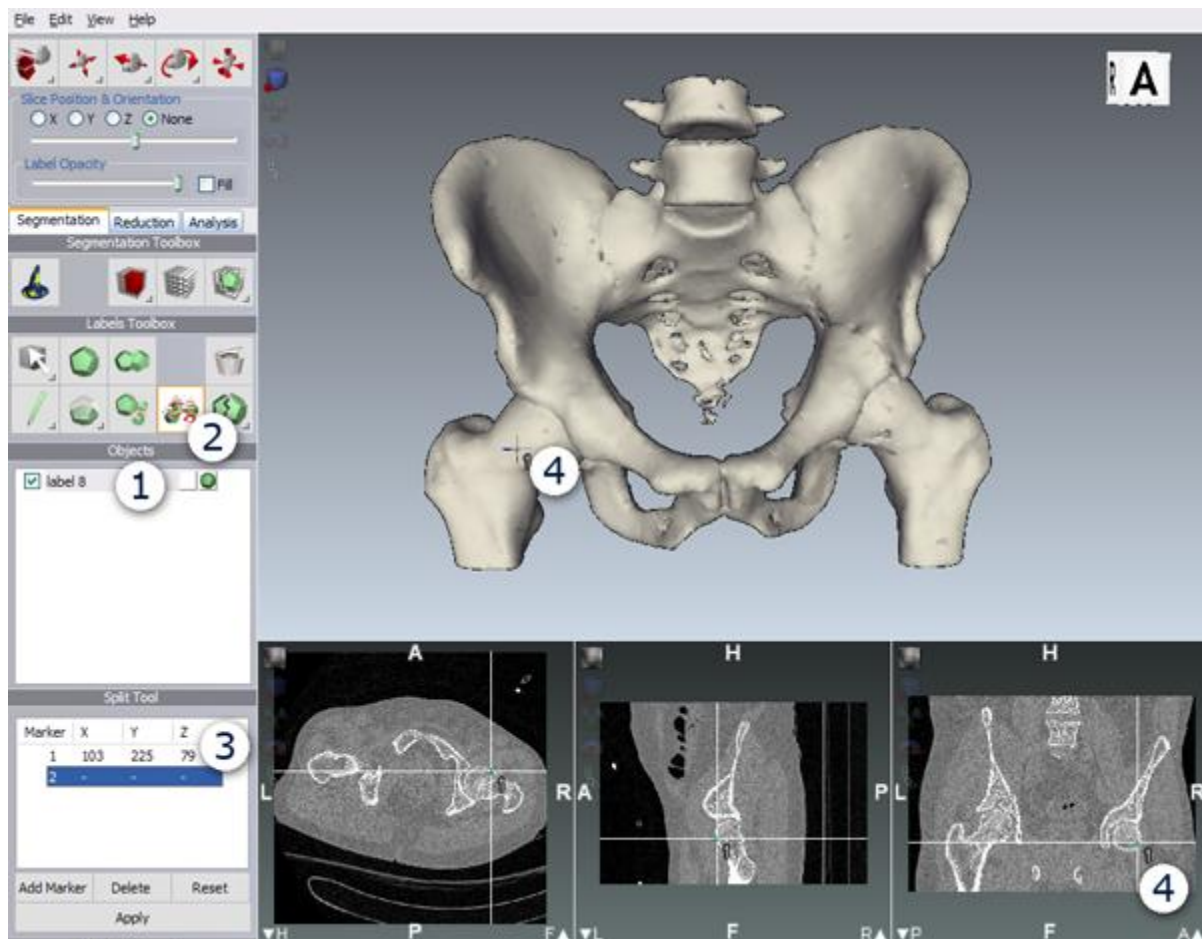

1. Select a label to work on. This can be done by clicking on the item in Objects list, or by activating the Select Tool and clicking on the desired label in 3D view.
2. Select Split Tool. The Split Tool panel will appear bellow. The panel contains list of all markers, buttons for editing markers, and a button for applying the filter.
3. Select one of the markers in the markers list. Double click will navigate Dataset view to that marker.
4. Click on the part which should become a separate label. This can be done either in 3D view or in Dataset view. When working in former the point might be moved from click location as to find the optimum placement based on the Dataset. Verify that point is still on or inside the part you clicked on.
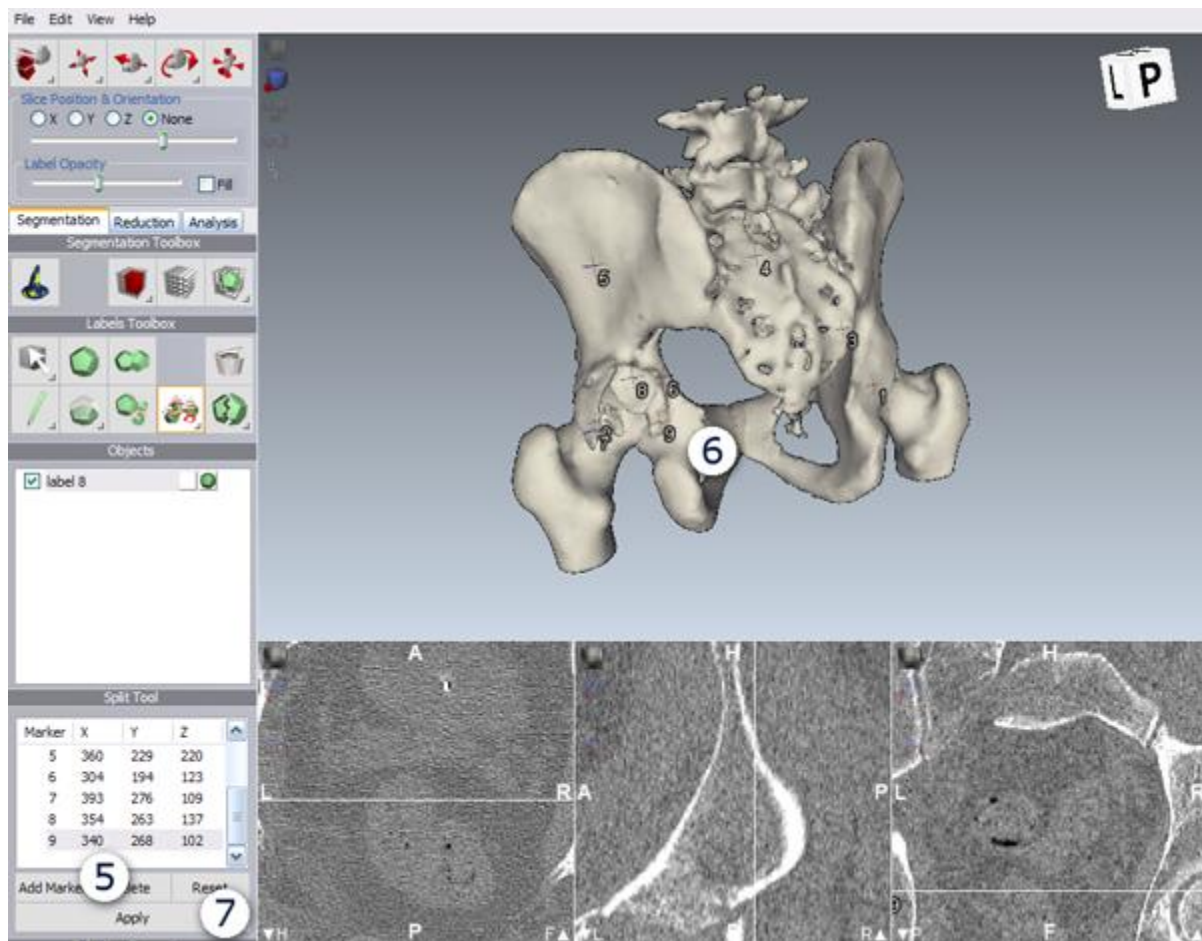

5. New markers can be added by pressing Add Marker and
6. defining the marker as presented in step number 4. Repeat steps 5 and 6 for each part which should be separated.
7. Press Apply. Depending on label and dataset size filter processing may take some time.
8. Sometimes the Split Tool doesn't separate some parts as expected. Solution is to either Undo the step and position the markers better or in this case where part has split into two labels (bone3, bone4) process it further. Select the bones which belong together and
9. click on Merge button. This will merge only the two labels.
In the image above is the final result. It shows merged labels. If some part of the label was split incorrectly it can always be fixed by merging the labels and re-applying the split tool only on that particular label. Also the label can be further divided by using the Split tool on it even without the Merge.

Cut Tool Example

This is a step-by-step example of Cut Tool usage on a case of splitting existing pelvis label into two new labels creating an artificial posterior column fracture.

Cut Tool can be used to cut away parts of label. The cut is made by defining a single or multiple dividers drawn in 3D view. Starting point for this example is a label obtained from Segmentation Wizard.
1. Select a label to work on. This can be done by clicking on the item in Objects list, or by activating the Select Tool and clicking on the desired label in 3D view.
2. Select Cut Tool. The Cut Tool panel will appear bellow. The panel contains list of all dividers, buttons for editing dividers, setting the selected volume and a button for applying the filter.
3. Rotate and align the view. Cut will be made perpendicular to view direction.
4. Draw the first divider by clicking points in the view area. Divider will split the label. Existing points in the divider can be moved; however it is currently not possible to remove them. Entire divider has to be re-drawn: use Delete followed by an Add Divider to start drawing divider from scratch.
5. Divider plane can be seen on a viewpoint change. Note that divider can be modified only in initial view for the specific divider. In in case one of the divider points is clicked view will be changed back to initial view for that divider. Double click on the divider in the divider list in tool panel will also activate the divider initial view.
6. Image above shows what would happen in case Apply button was pressed at this moment (Do not press the Apply button). Left side was split together with right posterior column. One way to proceed would be to select the white label and apply separate on it. Since parts we are interested in are not touching each other they will split just fine. After that desired parts can be merged using Merge. For the purpose of this example we will proceed in another way.
7. Rotate view to Anterior position.
8. Click on Add Divider to add another divider.
9. Draw the divider.
10. The two dividers divide space into 4 volumes. To specify which of the four volumes should be separated click on Set button and
11. define the point in the volume which should be separated by clicking on it in the 3D view. The element is marked with green sphere.
12. Press Apply button. Final result is displayed in the image below.
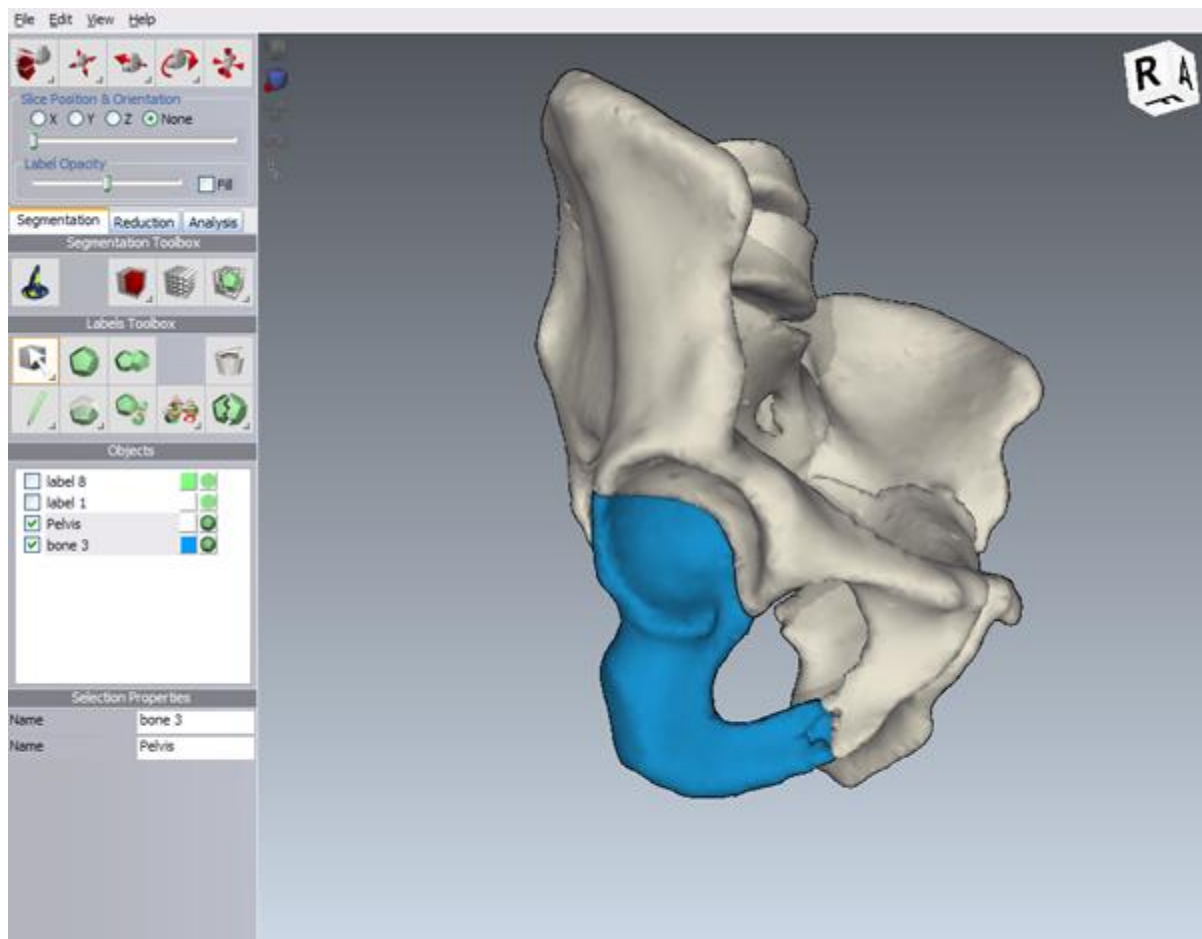

Reduction Toolbox

Select Tool

Click on object to select it. Hold Shift while clicking to add to selection or Ctrl to remove object from selection.

Shortcut: Q

Translate Tool

Click and drag on handles to translate a selected object.

Shortcut: W

Move Widget

Translation widget can be used in following ways:

- Dragging one of the arrows will move object in the direction of the arrow.
- Dragging cube in the center will move the selected object to the surface of the object below the mouse cursor.
- Dragging near the center will move the object parallel to the screen surface.

Pivot Tool

Shortcut: E

Click and drag on handles to change center of rotation.

Pivot Widget

Pivot widget can be used in following ways:

- Dragging one of the lines will move object in the direction of the line.

- Dragging cube in the center will move the pivot to the surface of the object below the mouse cursor.

- Dragging near the center will move the pivot parallel to the screen surface.

*Rotate Tool*

Shortcut: R

Click and drag the handles to rotate selected object.

Rotation Widget

Rotate widget can be used in following ways:

- Dragging one of the circles will rotate object in the axis of that circle.
- Dragging the outermost circle will rotate the object in the axis perpendicular to the screen.
- Dragging near the center of the widget will rotate object freely.

Reset

Reset Transformation.

Add Screw Tool

Click on scene to add a new screw. Once screw is created Screw Widget can be used to edit its placement.

Add Fixation Plate Tool

Click on scene to add a new fixation plate. Once fixation plate is created Fixation Plate Widget can be used to edit its placement.

Delete Object

Delete selected fixation plate or screw.

Screw Widget

Screw widget is a widget for editing screw length and its placement.
It is displayed for every selected screw in form of arrows and balls. Those act as a handle and can be clicked and moved with the mouse:
Direction Handle

- When ball above the entry point arrow is clicked direction indicator is shown enabling change of direction. Screw will automatically adjust the length to the new exit point.

Screw widget

- When screw exit point arrow is dragged screw exit point is changed.
- When screw entry point arrow is dragged entry position is changed and either:
 - direction is changed so that exit point remains the same (when exit point has been previously manipulated)
  - direction is perpendicular to the normal at new entry point (when screw direction has been previously manipulated)
- Holes in all fixation plates elements contain placement handle. When clicked screw will be placed in fixation plate hole.

Fixation Plate Widget
Fixation Plate Widget

Fixation plate widget is a widget for editing fixation plate placement. It is displayed for every selected fixation plate in a form of set of arrows. The arrows act as a handles and can be clicked on and dragged with the mouse:

- Indigo colored arrows annotate existing placement points. By dragging them on a bone fixation plate will change the shape. Dragging the placement arrow off the object will delete it.
- Clicking and dragging the green arrow will add a new placement point at the position of the arrow. This can be used to extend the fixation plate without changing the existing shape, when clicking on arrows on either extreme, or to control placement more precise, when clicking one of the inner arrows.

Objects
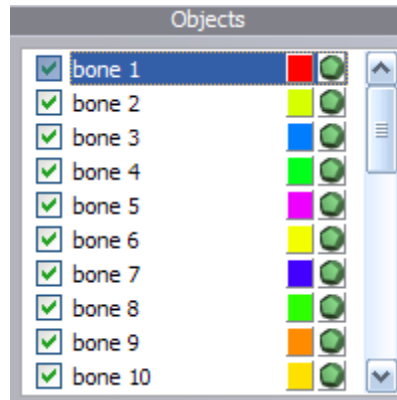

Objects list

Objects box contains list of all labels, fixation plates and screws in the document. Each object is represented by one row in the list and contains following information:

- **Visibility**. Object is visible when check box is checked.
- **Name**
- **Color**. Color can be changed by clicking on the color button.
- **3D mesh status** for labels or object icon for fixation plates and screws. 3D mesh status shows the status of 3D mesh object in relation to the voxel data of a label. There are 4 status icons:

  Mesh is build and it reflects current state of the label.

  Label does not contain enough voxels to build mesh from it.

  Mesh is not build or contains old state of the label. Build is required. Build process can be started by clicking on the icon.

  Mesh is being built.

  Mesh is already build, building collision detection mesh.

Selection Properties
Properties for selected Screw

Selection contains properties of selected object or objects. Some of the properties can be modified by typing in new value.

View Area

View area contains panes with views onto the document. Based on selected layout there is one or up to four panes displayed at the same time. View layout can be modified by selecting desired item from the *View|Layout* menu. Press spacebar in one of the panes to toggle between single pane layout and

multiple view layout.
Single Pane Layout
Four Panes Split Bottom
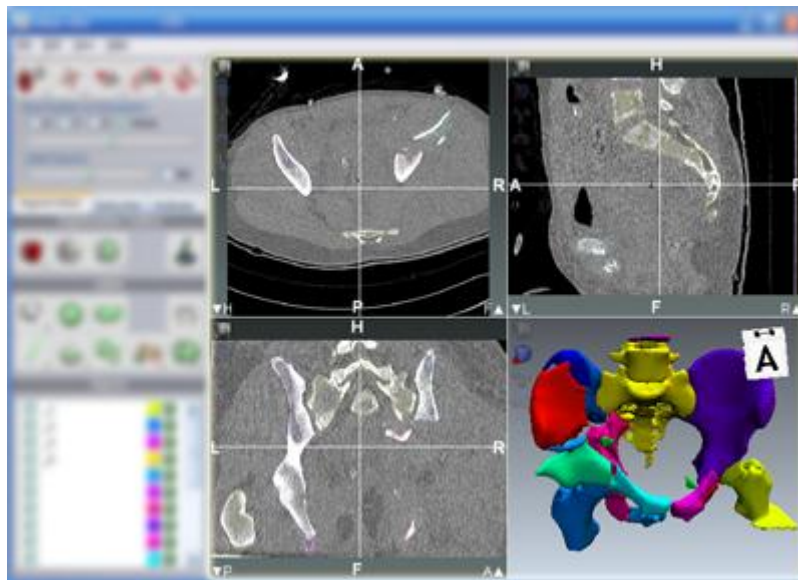

Four Panes

View Types

View displays visualization of document.

Based on view type visualization focus on different aspects of the data. View type of selected pane can be modifed by clicking on one of the options in *Views|Pane Contents*. Alternativelly view type icon can be clicked inside any view. The view type icons are located on the top left hand side corner of every view.

View type icons

Dataset View
Dataset view displays an orthogonal cross-section trough the dataset. Three orientations are possible. This view type can be used for [Segmentation](#).

3D View
3D view displays segmented objects as 3D meshes. This is primary view for [Reduction](#).

X-Ray View

X-Ray view displays X-Ray simulation based on 3D mesh objects. X Ray simulation does not give physically accurate image as it is based on following assumptions:

- All objects are of homogeneous material. Attenuation depends only on thickness.
- Visualization is based on 3D mesh objects. It does not include data that is present in the original dataset, but has not been captured by segmentation. Cracks than have not been captured in the process of segmentation will not be visible.

Cutaway View

Cutaway view display section trough the 3D model following the screw axis.
A screw has to be selected for this view to work.

CAD View

CAD view shows fixation plate from different sides in orthographic projection. This view can be used as a reference for bending the plate.
A fixation plate has to be selected for this view to work.

Lock Display Scale to 1:1

By selecting this option fixation plate is displayed on screen in real size.

Operating system does not provide accurate information on display device physical size. To get scaling to work correctly display has to be calibrated. Calibration is done in options: *Edit|Options|Display|Calibration* by entering pixel vertical and horizontal size. In case this information is not available physical display device width or resolution can be specified to calculate the pixels size.

Main Menu

File

New	Create a new document. Dialog will be displayed to select dataset files location.
Open	Load existing EBS document. EBS documents have .ebs extension.
Save	Save document under existing name.
Save	Save document under a different name.
Export	Export 3D mesh objects into COLLADA file. All visible screws, fixation plates and labels with 3D mesh representation are exported. The unit of exported scene is millimeter.
DICOM Files|Show Info	Show status of dataset file with source location of dataset files.
DICOM Files|Set Dataset Path	Set location of the dataset files. Available only in cases when the dataset path specified in document is invalid.
DICOM Files|Copy Dataset Files	Copy dataset files referenced in the document to arbitrary folder.
DICOM Files|Move Dataset Files	Move dataset files referenced in the document to arbitrary folder.
Show Metadata	Display DICOM metadata defined in currently loaded dataset. DICOM metadata contain information about the patient and examination details.
Exit	Exit the application.

Edit

Undo	Undo command.
Redo	Redo undone command.
Clear Undo Buffer	This command will release memory used by undo steps. It will also revert filtered dataset to initial state. This command can not be undone. Due to large size of data EBS might sometime not be able to perform operation for the lack of memory. To release unused memory use *Clear Undo Buffer* and try to execute operation again.
Options	Display options dialog.

View

Layout	Submenu item selects one of the available view layouts.
Pane Contents	Submenu item selects one of the available view types for the selected view pane.

Stereo	Enable anaglyph stereo view. Menu has a check box when stereo is enabled.
Eye Separation	Commands under this menu can be used to change the stereo eye separation.
Rebuild 3D objects	Rebuild 3D mesh objects for all the labels.

Help

Contents	Display help contents.
Activation	Activate EBS by sending serial number to the EBS activation service. To access full feature set EBS has to be [activated]().
About	Display application information.

User Interaction

EBS makes a distinction between three types of user interaction modes.
In all of the tree cases is expected that objects to act uppon, in case operation expects some objects as an input that is, are already selected before action is triggered.

Command

Command is executed as soon as button is clicked or menu item selected.

Command button for view-point reset.

Tool

Tool is state of the input and operations are executed only when mouse is clicked or dragged in one of the views. Each tool supports only certain view types. Tool buttons are denoted by triangle icon in bottom right hand corner. Only one tool can be active at any time.

Tool button for view panning; note the triangle.

31

Widget

Widget is a visual element that is drawn inside view and can be manipulated by clicking or dragging on its handle. As a general rule when both tool is active and widget is present widget has a priority i.e. when mouse is clicked on the widget handle widget will accept the action.
Translate object and viewpoint orientation widgets inside 3D view.

Options Dialog

Use options dialog to set application preferences.

Anaglyph Stereo

EBS supports 3D stereoscopic display by using anaglyph stereo glasses. Red-cyan colored glasses with red filter over left eye are required.

Anaglyph Stereo glasses.

Stereo view can be enabled in the options dialog: Edit|Options|View|Stereo or trough the View|Stereo menu.

The stereo effect depends on eye separation. It is advisable that you manually change the eye separation untill image is comfortable to view. The eye separation can be changed using F5 and F6 shortcut keys or by using the Stereo options panel.

Turning on stereo view might decrease color saturation of certain objects to enhance the stereoscopy effect.

Collision Detection

Collision detection prevents moving 3D mesh models into each other.

To enable special processing has to be done on mesh objects. The processing step is done in parallel to building mesh.

For collision detection to work NVIDIA® PhysX™ system software hass to be installed: http://www.nvidia.com/object/physx_9.09.0408_whql.html . Note that no special hardware is required to run this software.

3D Connexion mouse

EBS supports 3DConnexion input devices for changing viewpoint and moving objects in the 3D scene.

See the 3DConnexion web site for for details on available models: http://www.3dconnexion.com/ .

Tasks

EBS workflow comprises of following steps:

- Importing examination and creation of 3D mesh model: Segmentation
- Reduction and fixation using 3D mesh model: Reduction
- Analysis of the model: Analysis

Segmentation

Segmentation is a process of building 3D mesh model from examination in form of volumetric image - stack of image slices. Steps of segmentation are outlined below.

Importing Examination

A first step is to import examination data stored in DICOM format. Examination is loaded by selecting *File|New...* menu and pointing to folder with examination. With option "Include Sub-Folders" all sub-folders of selected folder will be scanned for images. In case there is more than one dataset found in specified folder selection dialog box will appear prompting to select one of the available datasets. Once dataset is loaded it can be viewed in dataset views.

DICOM metadata such as more detailed patient info and scanning parameters are available trough the menu *File|Show Metadata...*.

Menu *File|DICOM Files|Show Info...* displays short info about the state of dataset and where the images were loaded from. This might be useful moving .ebs documents to a different location.

Location of DICOM files is stored in .ebs document as a relative path reference. When document is saved to different device or media user must take care that DICOM files which document references are moved too. To modify the path to DICOM files *File|DICOM Files|Set Dataset Path...* can be used.

There are two utility commands to copy or move referenced DICOM files to user specified folder under *FIle|DICOM Files*.

Filtering Dataset

Based on scanning protocol used, data might contain too much noise to proceed with segmentation. By filtering dataset high frequency noise is removed. More the data is smoothed, easier will it will be to process further, but possibly important details might be lost.
Filter dialog is shown by clicking the *Filter Dataset* button. There are three smoothing filters available:

- Recursive Gaussian
- Gradient Anisotropic Diffusion
- Curvature Anisotropic Diffusion

Please consult ITK documentation about filter details.

Region Of Interest (ROI)

Processing time increases with dataset size. In case only part of dataset contains structures of interest it is possible to ignore irrelevant parts by defining sub region of the dataset where on which filtering is performed - ROI. ROI is used in Segmentation and some other filters.

Segmentation

Segmentation tags parts of dataset image which contain tissue of interest. Bone extraction is done with value thresholding followed by optional post processing. Segmentation tool is activated with

Segment Tool button.

With segmentation parts of dataset are selected which contain image. Simple thresholding is used to define areas. There are also three options for object post processing.

Further Processing

Before reconstruction can start bone fragments have to be separated so they can be manipulated independently. Full set of functions available for that purpose is in [Segmentation Toolbox](#).

Reduction

Reduction is done by moving the bone fragments and adding implants in form of fixation plates and screws.

The tools for reduction are available in [Reduction Toolbox](#) .

Activation

To access full functionality EBS requires to to be activated.
Following features are not available without activation:

- Creation of new document
- Saving of existing document
- Export

EBS can be activated by filling out a form under *Help|Activate* menu. The dialog will appear whith following information:

- **Computer ID** is unique id of a computer EBS runs on. The data is prefilled and can not be modified. Software has to be activated on each computer separatelly.
- **Serial Number** is a serial number provided to you by Ekliptik.
- **Name, Company** are the custom data describing user and company.
- **Email** is the address which will be used to send activation notification.

Once all of the above data are entered pressing *Get Activation Key* will connect to EBS activation service and request activation key. After a few moments key is automatically filled in and EBS is activated. In case activation fails error message box appears. In case the activation error persists please contact customer support: support@ekliptik.si.

Activation requires an active Interent connection. No other data then the data visible in the Activation dialog is transfered to activation service during activation.
